40%

de la población mundial está en riesgo de contraer dengue.

390 millones de infecciones de dengue cada año.

84 países están afectados por el Zika.

Cada 4 minutos un caso de chikungunya es confirmado.

En 2016 se presentaron cerca de 100.000 casos de dengue en Colombia; 28 mil en Antioquia y 18 mil en Medellín.

WOLBACHIA

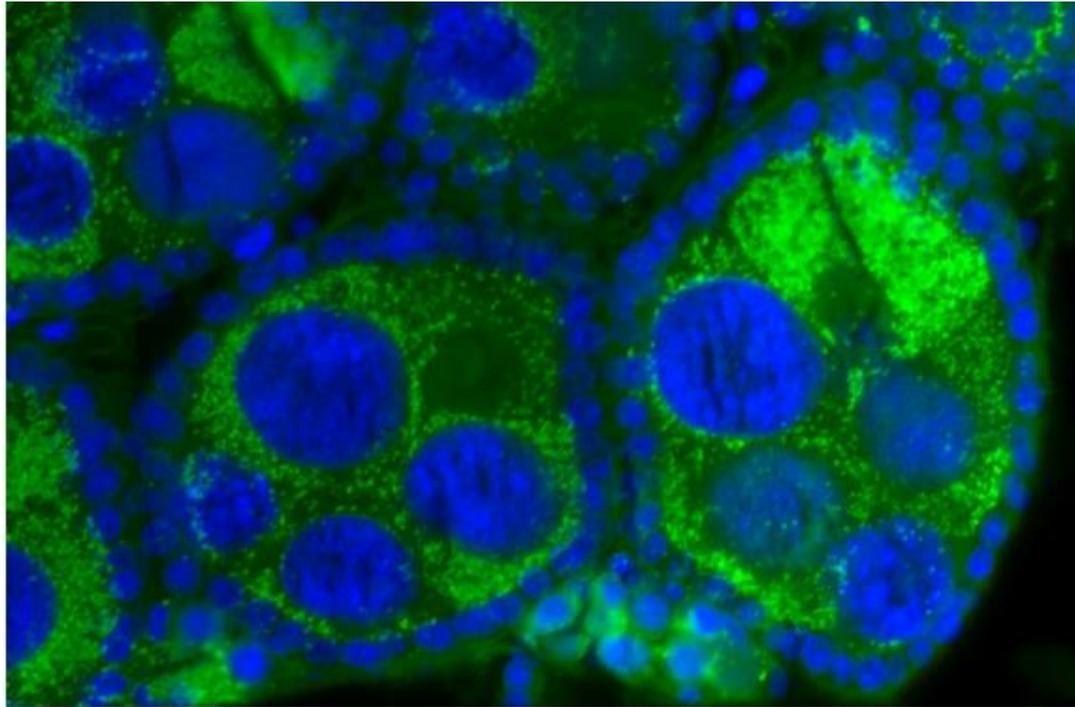

Imagen microscópica de los ovarios de un mosquito. En azul, al ADN del insecto, en verde, la bacteria 'Wolbachia'. /Itñaki Iturbe-Ormaetxe Eliminatedengue.com

Kingdom: Bacteria
Phylum: Proteobacteria
Class: Alphaproteobacteria
Order: Rickettsiales (2 families)
Family: Anaplasmataceae (4 genus)
Genus: *Wolbachia* (3 species)
Type species: *W. pipientis* (1936)
W. melophagi
W. persica (1961)

Wolbachia spp.

- **Obligate intracellular bacteria (Symbiont)**
- **Maternally transmitted**
- **It is all major insect orders**
- **Not culturable outside of host**
- **Is compatible with a broad range of hosts**
- **Produces a range of effects that can be used for disease control:**

Abstract

Background

New approaches to preventing chikungunya virus (CHIKV) are needed because current methods are limited to controlling mosquito populations, and they have not prevented the invasion of this virus into new locales, nor have they been sufficient to control the virus upon arrival. A promising candidate for arbovirus control and prevention relies on the introduction of the intracellular bacterium *Wolbachia* into *Aedes aegypti* mosquitoes. This primarily has been proposed as a tool to control dengue virus (DENV) transmission; however, evidence suggests *Wolbachia* infections confer protection for *Ae. aegypti* against CHIKV. Although this approach holds much promise for limiting virus transmission, at present our understanding of the ability of CHIKV to infect, disseminate, and be transmitted by wMel-infected *Ae. aegypti* currently being used at *Wolbachia* release sites is limited.

FIRST MEETING OF THE TECHNICAL ADVISORY GROUP ON PUBLIC HEALTH ENTOMOLOGY

PAN AMERICAN HEALTH ORGANIZATION

SUMMARY

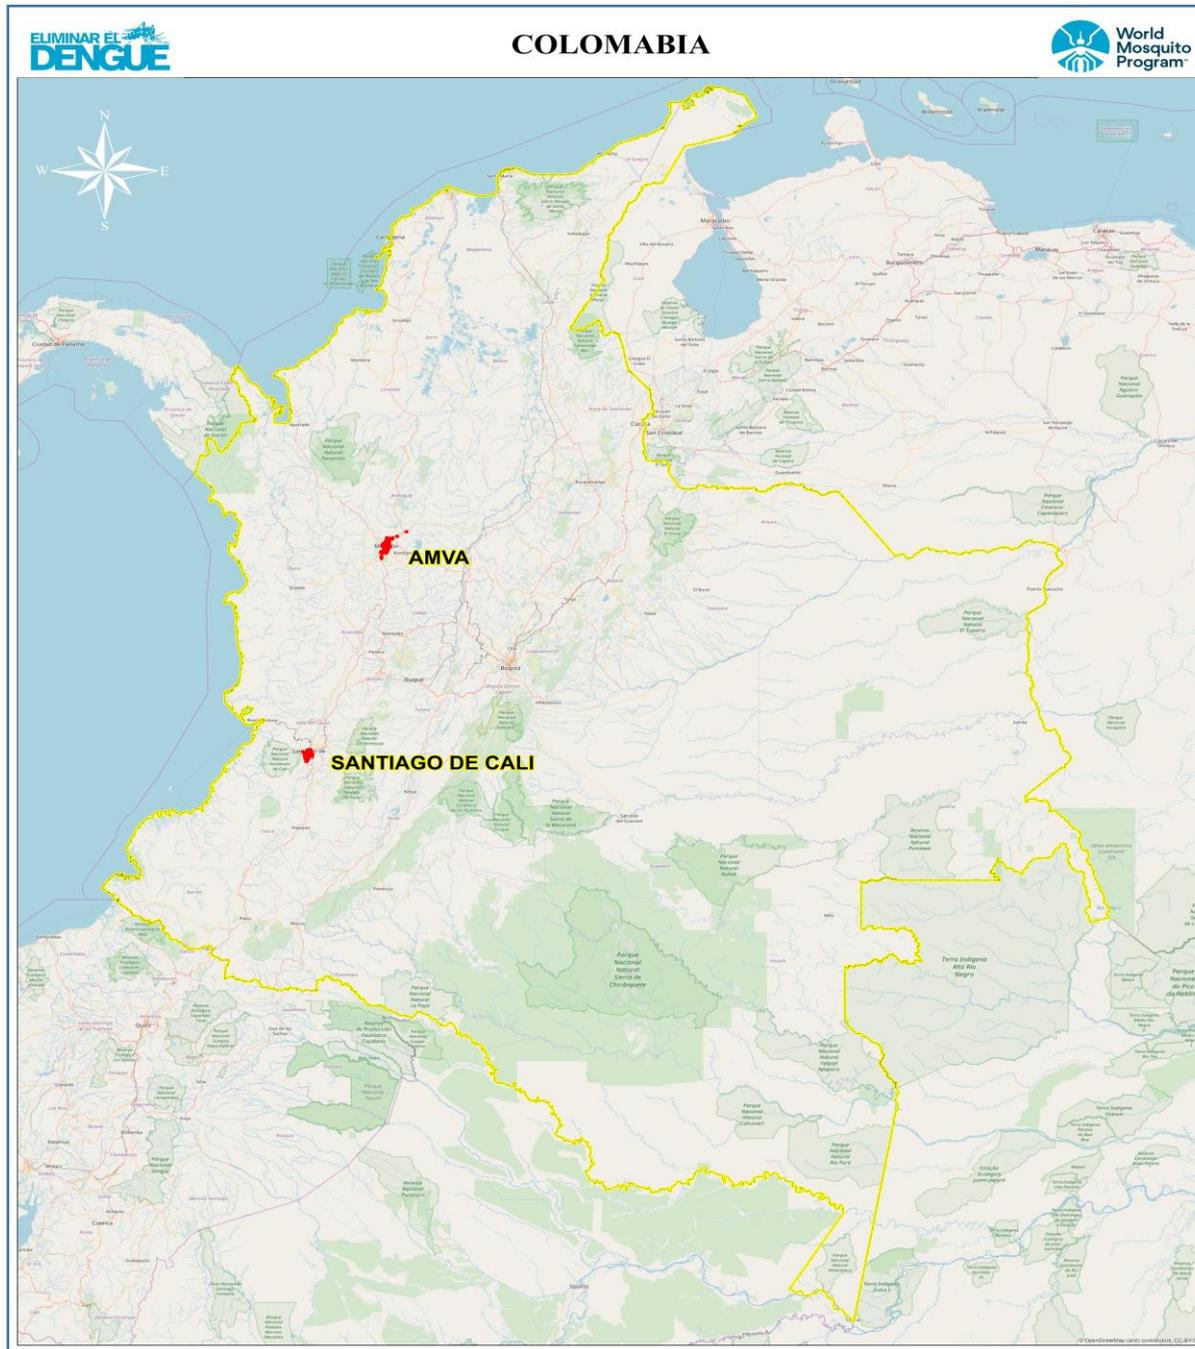

The first meeting of the Technical Advisory Group on Public Health Entomology (TAG PHE), was held from 8 to 10 March 2016 at the PAHO headquarters in Washington, DC. The topics discussed covered two scenarios: 1) vector control and prevention actions in regards to the current public health emergency of international concern (PHEIC) declared by WHO on the epidemic of Zika virus infections in the Americas, and 2) review and analysis of the actions that can be implemented in the medium and long term for the prevention and control of vectors responsible for vector-borne diseases (VBD) in the Americas.

- **Encourage** the rapid, robust and accelerated evaluation of new and supplemental tools for *Aedes* control, such as *Wolbachia* infections and genetically modified insect technology to ensure adequate technical cooperation and funding for this purpose.

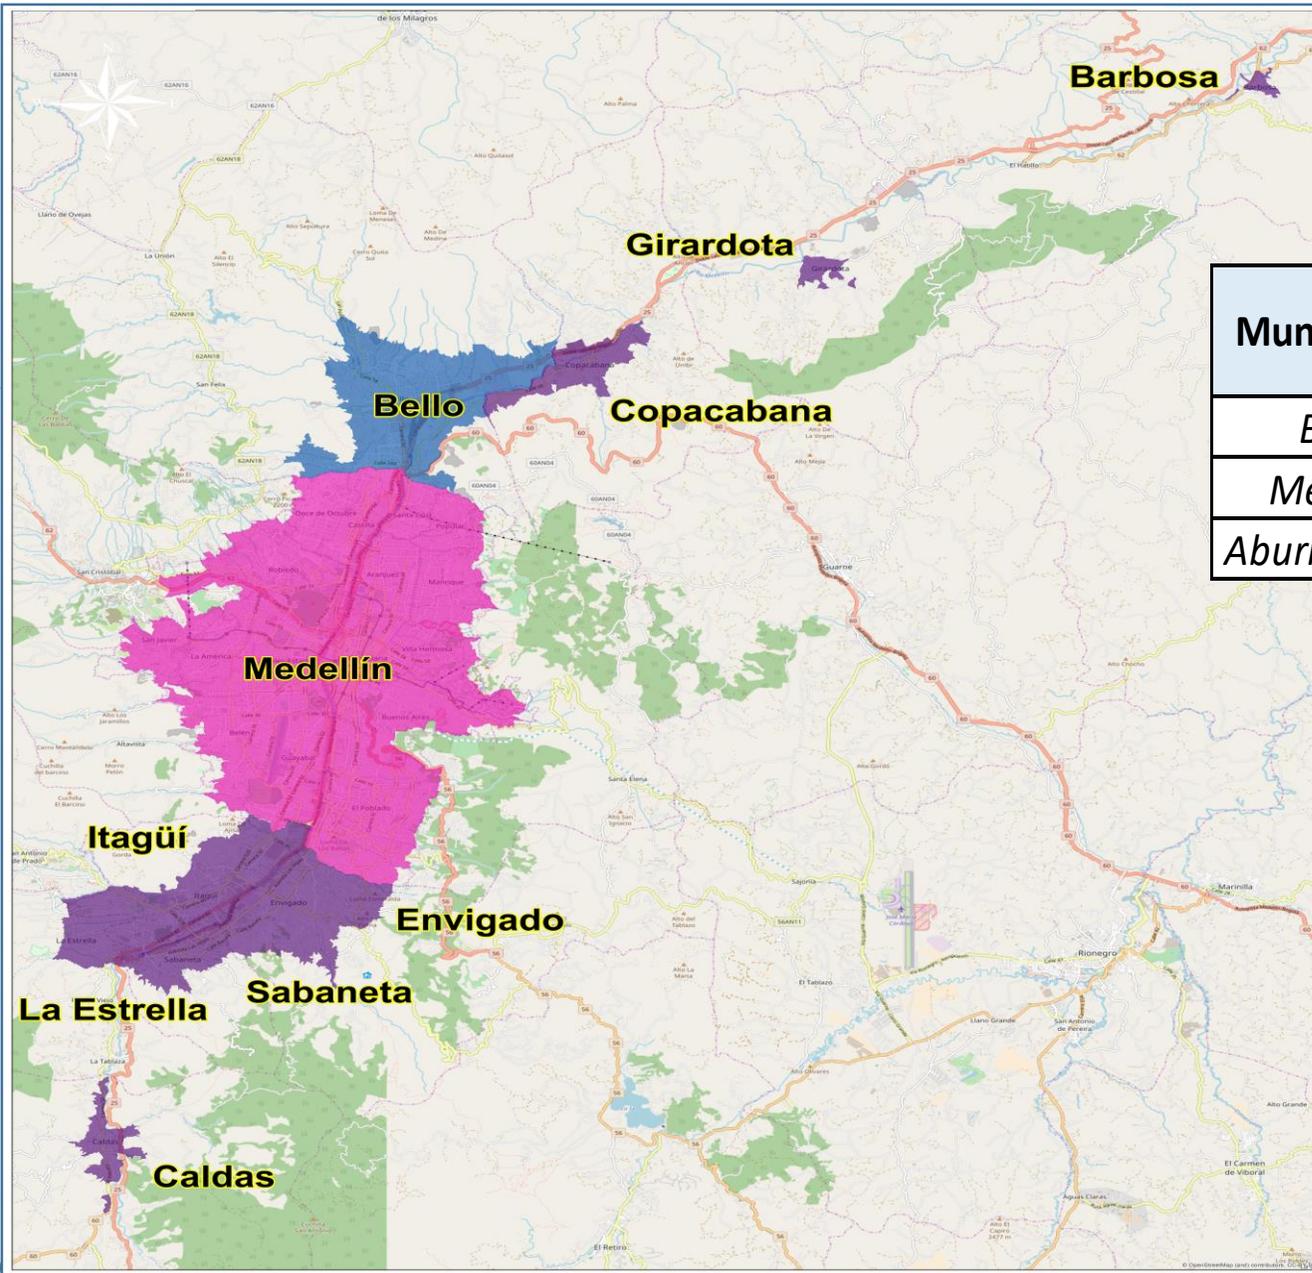

MONITORING AND EVALUATION

- **Develop and provide** a protocol for penetration testing of insecticides, and testing of biological efficacy, especially in countries where the situation of insecticide resistance is unknown.
- **Evaluate** the actions of vector control, field operations, work equipment and operational procedures used in prevention and control activities; in terms of impact of actions and cost-effectiveness, and the measured impact on disease transmission and incidence. The method and evaluation of most-productive mosquito larval containers should be included.
- **The countries should support the evaluation of new tools, without losing focus on the emergency and its corresponding response to their level of scale, feasibility, cost effectiveness and acceptability by the community.**

The Burden of Dengue and the Financial Cost to Colombia, 2010–2012

Raúl Castro Rodríguez,* Gabriel Carrasquilla, Alexandra Porras, Katia Galera-Gelvez,
Juan Guillermo Lopez Yescas, and Jorge A. Rueda-Gallardo

*Department of Economics, Universidad de los Andes, Bogotá, Colombia; Centro de Estudios e Investigación en Salud (CEIS),

Sanofi Pasteur Latin America, Mexico City, Mexico*

Abstract. Data on the burden of dengue and its economic costs can help guide health policy decisions. However, little reliable information is available for Colombia. We therefore calculated the burden of the disease, expressed in disability-adjusted life years (DALYs), for two scenarios: endemic years (average number of cases in non-epidemic years 2011 and 2012) and an epidemic year (2010, when the highest number of dengue cases was reported in the study period). We also estimated the total economic cost of the disease (U.S. dollars at the average exchange rate for 2012), including indirect costs to households derived from expenses such as preventing entry of mosquitos into the home and costs to government arising from direct, indirect, and prevention and monitoring activities, as well as the direct medical and non-medical costs. In the epidemic year 2010, 1,198.73 DALYs were lost per million inhabitants versus 83.88 in endemic years. The total financial cost of the disease in Colombia from a societal perspective was US\$167.8 million for 2010, US\$129.9 million for 2011, and US\$131.7 million for 2012. The cost of mosquito prevention borne by households was a major cost driver (accounting for 46% of the overall cost in 2010, 62% in 2011, and 64% in 2012).

COMUNICACIÓN BREVE

Presencia de *Aedes (Stegomyia) aegypti* (Linnaeus, 1762) y su infección natural con el virus del dengue en alturas no registradas para Colombia

Freddy Ruiz-López¹, Ana González-Mazo¹, Andrés Vélez-Mira¹, Giovan F. Gómez¹,
Luisa Zuleta^{1,2}, Sandra Uribe^{1,2}, Iván Darío Vélez-Bernal¹

¹ Programa de Estudio y Control de Enfermedades Tropicales, PECET, Universidad de Antioquia, Medellín, Colombia

² Grupo de Investigación en Sistemática Molecular, Universidad Nacional de Colombia, Medellín, Colombia

Introducción. *Aedes aegypti* es el principal vector de fiebre amarilla urbana, dengue, chikungunya y zika. Se ha demostrado que la distribución biogeográfica de esta especie se ha expandido debido al calentamiento global y a factores socioeconómicos y culturales. Los cambios en los patrones de la distribución altitudinal de este vector y su infección con el virus son prioridades de la investigación encaminada a desarrollar estrategias de vigilancia entomológica y virológica en salud pública.

Objetivo. Evaluar la presencia de *A. aegypti* y su infección natural por el virus del dengue en alturas superiores a los 1.800 msnm en dos municipios periféricos del Valle de Aburrá, Antioquia, Colombia.

Materiales y métodos. Se instalaron 21 ovitrampas en los municipios de Bello y San Pedro de los Milagros, en un rango altitudinal de 1.882 a 2.659 msnm. Los adultos que emergieron de las ovitrampas se evaluaron con reacción en cadena de la polimerasa en tiempo real (RT-PCR) para la detección del virus del dengue.

Resultados. Se recolectaron 367 adultos de *A. aegypti*, siete de los cuales se encontraron a una altitud de 2.302 msnm en Tierradentro, Bello. Se detectaron 12 especímenes de *A. aegypti* positivos para dengue serotipo 2 en el barrio París de Bello, a 1.984 msnm.

Conclusión. Por primera vez se registró *A. aegypti* a 2.302 msnm, la mayor altitud registrada para este vector en Colombia. De igual forma, se encontró infección con el virus del dengue a 1.984 msnm. Estos hallazgos son significativos, ya que determinan regiones de Colombia con riesgo potencial de transmisión autóctona de dengue y otros arbovirus por *A. aegypti*.

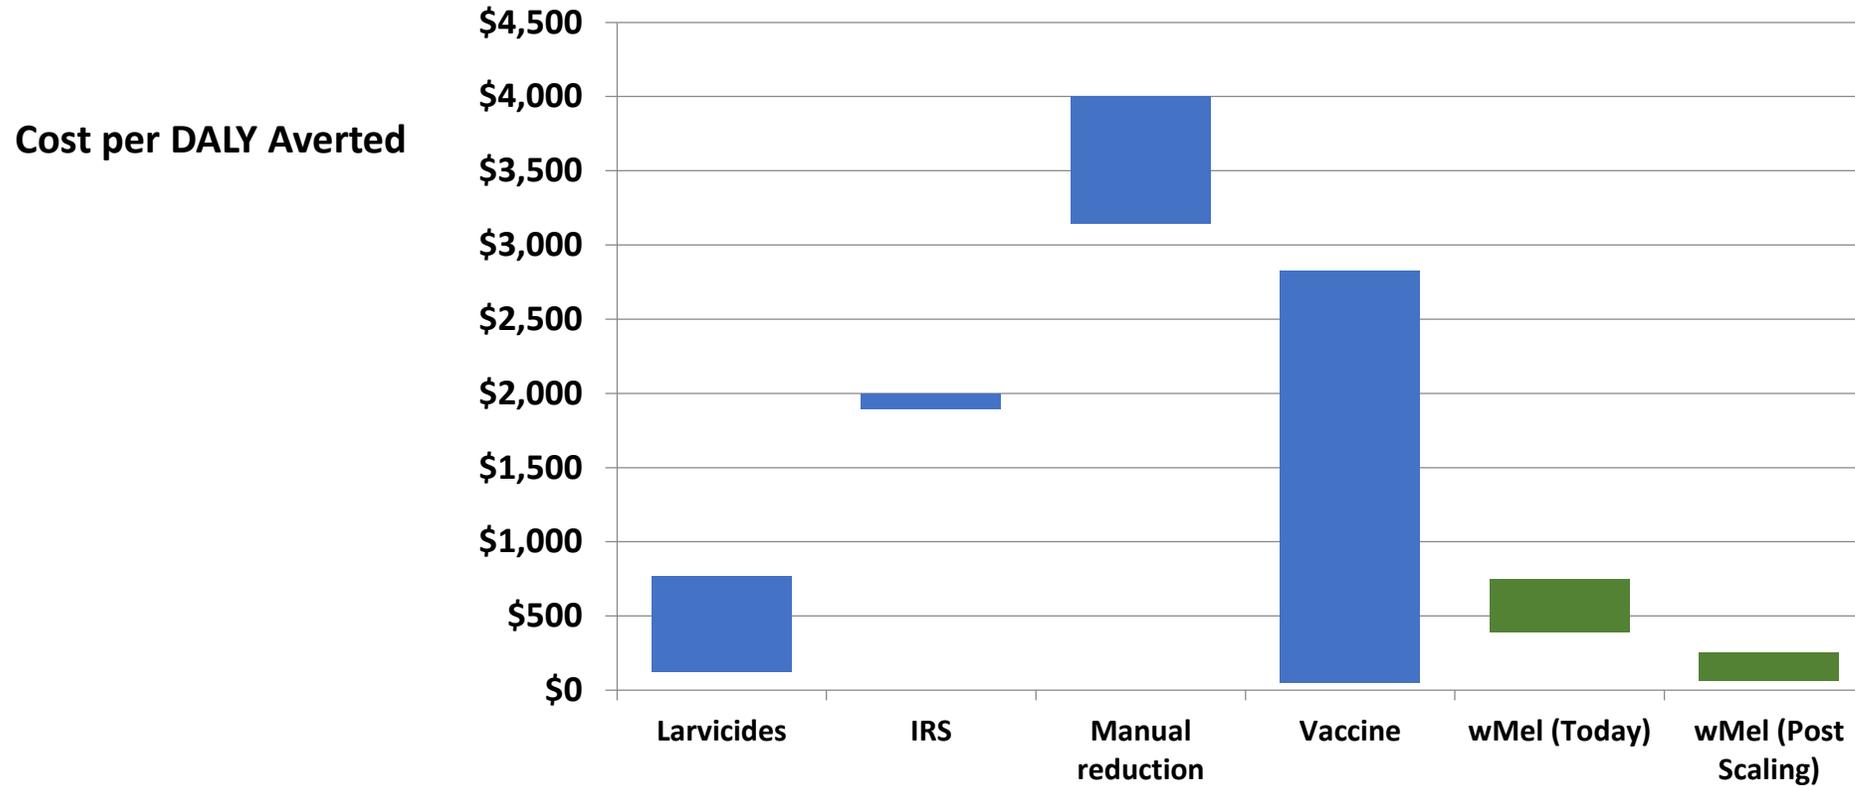

Palabras clave: *Aedes aegypti*, altitud, ubicaciones geográficas, dengue, Colombia.
